SeroELISA™ Chlamydia IgA

Enzyme-Linked Immunosorbent Assay (ELISA) for the detection of specific IgA antibodies to Chlamydia in human serum

Instruction Manual

Test kit for 96 determinations (Catalog No. 113-01)

For Research Use Only

Test kit for professional use only

Store at 2-8°C. Do Not Freeze

Intended Use

The SeroELISA™ Chlamydia IgA kit is intended for the determination of specific IgA antibodies to Chlamydia in a single human serum sample by an Enzyme-Linked Immunosorbent Assay (ELISA). For Research Use Only.

Introduction

Chlamydia is a gram-negative obligate intracellular bacteria that causes acute and chronic diseases in mammalian and avian species. The genus Chlamydia is comprised of four species: C. trachomatis, C. pneumoniae, C. psittaci and C. pecorum.

C. trachomatis is divided into 15 serovars (1). Serovars A, B, Ba and C are agents of trachoma (2), the leading cause of preventable blindness endemic in third world countries. Serovars L1-L3 are the agents of lymphogranuloma venereum. Serovars D-K are the common cause of sexually transmitted genital infection worldwide: cervicitis, endometritis/salpingitis (3) in females and urethritis (4) in both males and females. Endometritis/salpingitis can lead to tubal occlusion with a higher risk of extra uterine pregnancy and infertility. Genital infection may cause an acute and persistent infection occasionally without any clinical symptoms. Generally, these infections are treatable once they are diagnosed. However without any treatment the infection may progress to a severe chronic inflammation leading to infertility, ectopic pregnancy, induced abortion or premature delivery. Moreover, infants to infected mothers may be infected during birth, leading to conjunctivitis or pneumonia (5).

C. pneumoniae is an important respiratory pathogen in humans and causes up to 10% of community-acquired pneumonia cases. It has been associated with acute respiratory diseases, pneumonia, asthma, bronchitis, pharyngitis, acute chest syndrome of sickle cell disease, coronary heart disease, and Guillain-Barre syndrome (6).

C. psittaci infects a diverse range of host species from molluscs to birds to mammals and also causes severe pneumonia.

SeroELISA™ Chlamydia test employs the L2 serovar broadly reacting antigen of C. trachomatis. It will detect C. trachomatis, C. psittaci and C. pneumoniae (TWAR) antibodies.

Principle of Test

- Human serum to be tested is brought into contact with the antigenic material coating the microtiter wells. Specific antibody, if present in the patient serum will bind to the attached antigen, a complex is formed and all the serum components are washed away in the wash phase.
- Horseradish peroxidase (HRP) conjugated anti-human IgA (α chain specific) is added to the wells. If an antigen-antibody complex was formed in the previous step, the peroxidase conjugated antibody will bind to the antibody moiety of the complex. If no antigen-antibody complex was formed in the previous step, the conjugate is washed away in the wash phase.
- TMB-Substrate is added. A positive reaction is indicated by a blue to deep blue color which develops in the test wells following enzymatic
reaction of the peroxidase moiety with peroxide and the chromogen reactant. After the enzymatic reaction is stopped by an acidic solution, the absorbance of the test wells is determined at 450nm by a spectrophotometer.

- The absorbance at 450nm is indicative of IgA anti-Chlamydia titer in patient serum specimens.

### Assay Procedure

1. **Chlamydia Antigen Attached to Solid Phase (Ag)**
   - Serum positive for IgA Anti-Chlamydia (Ab1)
   - **AgAb1 Complex**

2. **AgAb1 Complex** + HRP Conjugated Anti-Human IgA (Ab2)
   - **AgAb1Ab2 Complex**

3. **AgAb1Ab2 Complex** + TMB-Substrate
   - **Blue Solution**
   - **Chromogen Stop Solution**
   - **Yellow Solution** (Absorbance Determination at 450nm)

### Warning and Precautions

- **Warning:** THE CHLAMYDIAL ANTIGENIC MATERIAL HAS BEEN INACTIVATED AND CONTAINS NO DETECTABLE LIVE ORGANISMS. HOWEVER, THE STRIPS SHOULD BE HANDLED AND DISPOSED OF AS WOULD ANY POTENTIALLY BIOHAZARDOUS LABORATORY MATERIAL.

- **Precautions:** This kit contains human sera which have been tested by FDA approved techniques, and found to be negative for HBV antigen and for HCV and HIV 1 and HIV 2 antibodies. Since no known method can offer complete assurance that products derived from human blood do not transmit infection, all human blood components supplied in this kit must be handled as potentially infectious serum or blood according to the recommendations published in the CDC/NIH manual "Biosafety in Micro Biological and Biomedical Laboratories, 1988”.

- Substrate/Chromogen Solution is an irritant material to skin and mucous membranes.

### Materials Required But Not Supplied

1. Perfectly clean test tubes for dilution of patient sera.
2. Adjustable micropipettes, or multichannel pipettes (5-50, 50-200 and 200-1000µl ranges) and disposable tips.
3. Disposable plastic pipettes (assorted sizes) and safety pipetting devices.
4. One liter volumetric flask.
5. One 50ml volumetric cylinder.
6. ELISA plate washer or wash bottle.
7. Paper towels or absorbent paper.
8. Vortex mixer.
9. A 37°C water bath with a lid, or a moisture chamber placed in a 37°C ± 1°C incubator.
10. ELISA-reader with 450nm filter.
11. Distilled or double deionized water for the dilution of Concentrated Wash Buffer.

### Storage and Shelf Life of Reagents

All the materials supplied should be stored at 2°C to 8°C. If kept at 2°C to 8°C the test reagents are stable until the expiry date indicated on the kit pack. Exposure of originally stoppered or sealed components to ambient temperature for a few hours will not cause damage to the reagents. **DO NOT FREEZE!**

When a kit is in use, the shelf life of the original material is 60 days from the day first opened. Once opened, the aluminum foil sachet containing the strips should be sealed with a tape. The dehydrating packet should not be removed.

### Specimen Collection

Serum specimens should be collected aseptically and stored at 2°C to 8°C with 0.05% sodium azide.
(NaN₃) as a preservative if they are to be tested within a few days. For longer periods, aliquots of serum specimens should be stored at -20°C. Since turbid or hemolytic serum samples may give less reproducible results, it is highly recommended that serum samples tested be clear and non-hemolytic.

**Assay Procedure**

**Notes:**
- The components of this kit have been tested as one unit. Do not mix components from different kit lots or other manufacturer's kits.
- All reagents should reach room temperature before use. Serum Diluent and Conjugate Diluent gelatinize when refrigerated. If needed, accelerate liquefaction by warming these components at 37°C for several minutes. Salt crystals may form in the Concentrated Wash Buffer when stored at 2° to 8°C. These crystals should be completely redissolved by warming at 37°C before dilution.
- Do not perform the test in the presence of reactive vapors (e.g. from acid, alkaline or aldehyde substances) or dust, since the enzymatic activity of the HRP conjugated Anti-Human IgA may be affected.
- Do not touch the top of the strips. Do not touch the edges of the wells with the pipette tips when dispensing reagents.
- Use disposable pipette tips. Avoid cross contamination between reagents.
- Tap vial lightly on hard surface to free liquid that might be entrapped in the cap.
- Avoid entrapping air bubbles in the wells.
- Dispense liquids slowly to avoid spraying.
- Positive Control, Low Positive Control and Negative Control sera should be run together with serum specimens each time the test is performed.
- One well per test should be used for a blank value each time the test is performed.
- All the procedure steps should be performed sequentially without interruption.

**Test Procedure – Manual**

**Automation protocol available upon request**

**A) Washing of Strips**

*Prewashing of strips is advisable but not mandatory. In any event, strips should be wet by Wash Buffer solution before application of test samples and dried by tapping them over clean absorbent paper prior to testing.*

If automatic ELISA plate washer is unavailable procedure should be performed as follows:

1. Remove required number of strips from their aluminum foil sachets and insert them in the plate frame.
2. Dilute the Concentrated Wash buffer 1:20 with distilled water.

*For Example: For one strip prepare 100ml of Wash Buffer (5ml Concentrated Wash Buffer with 95ml distilled water). Swirl gently for 20 minutes.*

Wash Buffer working solution should be prepared before use and excess discarded.
3. After the incubation fill each well with Wash Buffer solution up to the middle of the well.
4. Allow to soak for 2 minutes, then discard the strip contents. Repeat these steps two times.
5. Dry the top of the strips and frame by gently tapping them over clean absorbent paper.

**Complete washing of wells after incubation is essential for best results. Traces of Wash Buffer should not be left in the wells.**

**B) Incubation of Serum Samples and Controls**

6. Dilute each patient serum 1:64 with Serum Diluent as follows:
   - Add 10µl of patient serum to 150µl of Serum Diluent.
   - Add 30µl of 1:16 dilution to 90µl of Serum Diluent.

**Controls are provided in a ready-to-use form and should not be diluted.**

7. Pipette 50µl of ready-to-use Positive control, Low Positive Control, Negative Control and 1:64 patient serum dilution into corresponding separate wells of the test strips. Pipette 50µl of Serum Diluent into one well for blank value.

**Pipetting of controls and serum specimens into the wells should not exceed 10 minutes.**

8. Cover the strips with a plate cover and incubate for 30 minutes at 37°C in a moisture chamber.
9. Discard the liquid content of the wells. Wash the wells five times and dry as in steps A) 3-5.

**C) Incubation with Conjugate**

10. Pipette 50µl of ready to use HRP Conjugated Anti-Human IgA into each well.
11. Cover the strips with a plate cover and incubate for 30 minutes at 37°C in a moisture chamber.
12. Discard the liquid content of the wells, wash them five times and dry as in steps A) 3-5.

**D) Incubation with TMB-Substrate**

13. Pipette 100µl of TMB-Substrate into each well.
14. Cover the strips with a plate cover and incubate at room temperature for 30 minutes.
15. Stop the reaction by adding 100µl Stop Solution to each well.
16. Calibrate the spectrophotometer on the blank well. Determine the absorbance at 450nm and record the results.

*Immediate determination of the absorbance is advisable but not mandatory. Absorbance determination should not exceed 30 minutes, following stopping of chromogenic reaction.*

**Acceptability of Criteria of the Test**

A test-run is valid if:
- Positive Control absorbance is ≥0.8 at 450nm
• Low Positive Control absorbance is ≥0.4 at 450nm
• Negative Control absorbance is ≤0.15 at 450nm
If these conditions are not fulfilled, the test run is invalid and should be repeated.

Calculation of Cut-Off Value (COV)

The cut-off value is calculated according to the following formula:

\[ \text{COV} = 0.198 \times (\text{Pc} - \text{Nc}) + \text{Nc} \]

Pc = Absorbance of Positive Control at 450nm
Nc = Absorbance of Negative Control at 450nm

<table>

* Retest serum samples classified equivocal. If equivocal result is repeated testing of subsequent serum sample is recommended.

Performance Characteristics

SeroELISA™ Chlamydia test was compared to IPAzyme™ Chlamydia IgG/IgA test (Savyon Diagnostics product, Cat. No. 011-01) which is an accepted serological test for detection of IgA antibody to Chlamydia. The study population included patients with suspected Chlamydia infections as well as healthy individuals (n=200).

Overall agreement: \((189/200) \times 100 = 94.5\%\)

Cross Reaction

Hospitalized patients, infected with Neisseria gonorrhoea, Staphylococcus aureus and Peptostreptococcus anaerobius, who were diagnosed by commercial serology kits, were also tested with the SeroELISA Chlamydia kit. There was no significant cross-reactivity detected.

Significance of Results

Clinical experience indicates that IgA antibodies to Chlamydia may serve as a marker for active or chronic Chlamydia infection (3,11,12).

Endpoint Titer Determination

For monitoring of the immune profile of a patient, acute stage and convalescent serum samples should be compared. Endpoint titration of paired sera should be performed with both serum samples tested in the same run. The highest serum dilution with absorbance above the test cut-off value is the end titer.
